**AMPHETAMINE®**

Amphetamines are stimulants that speed up the body’s system. Amphetamines can come in the form of pills or powder. Many amphetamines are legally prescribed and used to treat attention deficit hyperactivity disorder. Common prescription amphetamines include methylphenidate (Ritalin® or Ritalin SR®), amphetamine and dextroamphetamine (Adderall®), and dextroamphetamine (Dexedrine®).

**EFFECTS**
The effects of amphetamines, like other stimulants, increases blood pressure, heart rate, alertness, attention, and energy. In addition, it increases blood glucose levels, opens the pathway of the respiratory system, and constricts blood vessels. Amphetamines produce increased wakefulness and focus in association with decreased fatigue and appetite. A sense of euphoria is often associated with the use of stimulants. Abuse of amphetamines can lead to dependence on the drug. In addition, high doses of the drug can result in dangerously high body temperature, irregular heart beat, cardiovascular failure, and lethal seizures.
INCIDENCE & PREVALENCE

According to the World Drug Report 2010, though amphetamine-groups substance use remain high in North America, a recent survey showed a decline in the use of amphetamines. Among the population aged 12 years and older, the annual prevalence of all stimulants use was reported as 1.5% in 2006, 1.2% in 2007, and 1.1% in 2008. Amongst 10th graders in Indiana there has been a gradual decrease in amphetamine use.

LAW & CRIMINAL JUSTICE

According to the U.S. Drug Enforcement Administration, amphetamines are classified as Schedule II stimulants, which means they have a high potential for abuse and limited medical uses. Pharmaceutical products are available only through a prescription that cannot be refilled.
